Title : Formation of Vitamin B₁₂ by Soil Bacteria

Orig Pub : Spisy vyd. prirodoved. fak. Masarykovy univ., 1956, No 8,
407-416

Abstract : The ability to synthesize vitamin B₁₂ was studied in 8 physiological groups of soil bacteria and 6 groups of morphologically different actinomycetes. Actinomycetes formed 0.4-0.8 γ/ml of the vitamin; ammonia fixing bacteria-- 0.39 γ/ml; bacterial decomposing cellulose -- 0.225 γ/ml. In these groups of bacteria the most active synthesis is noted in anaerobes. Nitrifiers and denitrifiers and bacteria decomposing urea did not synthesize vitamins, while bacteria of other groups studied have only weak synthetic activity (0.01 γ/ml).

A description is given of a case of simultaneous occurrence of an ovarian fibroma, hydrothorax dextra and ascites in a 48-year-old female patient, who completely recovered after operation was performed. In 4 months 65,200 ml. of fluid was drained off by tapping for alleviation. The diagnostic difficulties are discussed: in this patient they led to treatment for pulmonary tb and later on for lung tumour. Laparotomy resulted in a correct diagnosis and a successful treatment of the case.

1862. MORE HOMOGENEOUS CONTACT ROENTGEN IRRADIATION OF LARGE SKIN CANCERS - Nagykiterjedésű bőrrákok homogénebb kontakt röntgen besugárzása - Godan F. - MAG.ONKOL. 1958, 2/2 (69-76) Graphs 5

Irradiation of cancers of the skin of great extent with the moving beam of the Van der Plaats apparatus along a 'U'-shaped meander line affords a more homogeneous effect and better cosmetic results than does treatment by standing fields. In the latter, the margins of the adjacent fields overlap and there may be areas in which summated dose is double the desirable value. The results of this incorrect technique are often telangiectases, uneven cicatrizations and recurrences in the marginal parts. The technique of moving-beam pleurotherapy is as follows: the area of extension of the tumour is divided by the area of the standing irradiated field of the employed tube. Multiplication of the irradiation time of the dose for one field by this quotient gives the suitable length of the time of irradiation with the moving tube.

Whiteware

Lead- and boron-free glazes. YU. VA. TONKIN AND G. K.
GORD. *Latsijs PSK Zinatn Akad. Vses.* 1950, No. 12, pp.
108-111. The effects of alkali, Cu, Mg, Zn, Ba, Fe, P, B, Al, and
Si on glazes fired at 900° to 1000°C were studied. On the basis of
these studies, the following glazes were made and tested; they
are recommended for further study.

0.4 K ₂ O	0.05-0.07 Al ₂ O ₃	1.8 SiO ₂
0.15-0.2 CaO + MgO	0.05-0.07 Fe ₂ O ₃	
0.4-0.45 BaO + ZnO		

This glaze is clear and has a good luster. A thin layer gives little
noticeable crackle. A glaze with the same characteristics but
which can withstand 120° of temperature difference is as follows:

0.2-0.25 Na ₂ O	0.15-0.2 Al ₂ O ₃	3.0-3.2 SiO ₂
0-0.1 K ₂ O	0.15 Fe ₂ O ₃	0.4-0.5 B ₂ O ₃
0.15-0.2 CaO + MgO		
0.5-0.6 BaO + ZnO		

In the absence of Ba and Zn, the following glaze is suggested:

0.6-0.7 Na ₂ O + Na ₂ O	0.1 Al ₂ O ₃	1.8 SiO ₂
0.3-0.4 CaO + MgO	0.5-0.6 Fe ₂ O ₃	0.4-0.5 B ₂ O ₃

The following glaze will withstand 100° temperature difference:

0.4 Na ₂ O + K ₂ O	0.05-0.07 Al ₂ O ₃	2.0-2.5 SiO ₂
0.15-0.25 CaO + MgO	0.15-0.3 Fe ₂ O ₃	0.1-0.2 B ₂ O ₃
0.35-0.45 Fe ₂ O ₃ + ZnO

Godecki M. Notes on Overhead Travelling Crane Construction.

„Uwagi w sprawie konstrukcji suwnic” Bezpieczeństwo i Higiena Pracy Nr 3, 1951, pp 86—91, 8 figs.

Mechanization of indoor transport in industries by means of overhead travelling cranes is often the source of accidents caused by the faulty construction of certain elements of this equipment. The article deals with constructional solutions which would protect the operating personnel against accidents or professional diseases and in particular with the method of protecting by means of access to overhead cranes by ladders, gantries, platforms, with

proper overall dimensions of transport equipment, with the construction of operator's cabins and with proper lighting, visibility and air conditioning arrangement.

"Kabinie suwnic", Ochrona Pracy. No. 3, 1953, pp. 71-81, 18 figs.

(tab.

A discussion of technical factors in the construction of crane cabins, which are of fundamental influence in affecting hygienic working conditions for the crane operator. The size of the cabin must, to enable the operator to be seated, ensure a minimum of 0.8 m³ of free space between the controls. A surface of 1400 X 1650 mm. is laid down as the minimum floor-space. Such a type of cabin should be chosen as fits the conditions of work, which in turn determine the kind of housing and front the cabin should have. Consideration is also given to the problem of proper location of the cabin on the crane, with a view to securing safe working conditions. Requirements regarding illumination, and heating in the cabin are also discussed.

Title : Siloing of Summer Corn in the Conditions of Turkmenistan. A Preliminary Report.
Orig Pub. : Tr. Turkm. s.-kh. in-ta, 1957, 9, 415-419
Abstract : The article deals with the techniques of corn siloing under the conditions of high summer air temperatures and with the evaluation of summer corn silage. One kg of summer silage contains 0.25 feed units, of fall silage - 0.21. As compared to fall silage, summer silage contains more nutritive and mineral substances.

TITLE The Effect of Rolling Rate, Temperature, and Degree of Deformation in a Single Pass on the Specific Pressures Arising During Hot Rolling of Nickel and German Silver MN19 (Vliyaniye skorosti prokatki, temperatury i stepeni deformatsii za prokhod na udel'noye davleniye pri goryachey prokatke nikelya i mel khiora MN19)

PERIODICAL Tr. Gos. n. 1. proyekt. in-ta po obrabotke tsvetn. met., 1957, Nr 17, pp 5-18

ABSTRACT An investigation was carried out in order to establish the basic factors affecting the specific pressure (SP) which arises during hot rolling of nickel and German Silver (GS). Blanks with a cross section of 70x70 mm and an initial length of 300-350 mm were rolled in a two-high rolling mill with rolls having a diameter of 400 mm. It was established that at rolling velocities (RV) of 0.9, 2.2 and 3.5 m/sec, and reductions of 10, 20, and 30%, at temperatures ranging from 1200-1000°C in case of Ni and 1050-850° in the case of GS, the SP is proportional to

Card 1/3

137-58-b 12145

The Effect of Rolling Rate, Temperature, and Degree of Deformation (cont.)

the ultimate tensile strength (at a corresponding temperature of deformation) and may be determined by the formula: $p = C \cdot \sigma_v$. On the basis of experimental data the magnitude of the coefficient C was determined for various degrees of deformation and various RV's. If a rolling operation involves metal blanks and rolls with dimensions different than those employed in the experiment, the effect of these factors should be taken into consideration by introducing appropriate coefficients. At RV's from 0.9 m/sec to 3.5 m/sec and at 20% reduction of a Ni or GS blank in a single pass, the SP was determined as a linear function of the RV as expressed by the following linear equation: $p = p_{v0} + A \cdot \Delta V_x$ where A is a velocity coefficient which is equal to the slope of a straight line and which is found to be equal to 1.4 in case of Ni and 0.78 in the case of GS. It was established that the formulae of Gubkin, Tselikov, and Petrov are qualitatively correct in their consideration of the basic factors affecting the SP. In order to obtain accurate results, it is essential that correction coefficients, which have been determined for the SP formulae at RV's ranging from 0.9 to 3.5 m/sec, be introduced into the formulae presented above. Experimental rolling of Ni ingots was performed in the rolling shop of the Ordzhonikidze plant on a mill with rolls 566 mm in diameter at a RV of 0.8 m/sec in order to verify the correctness of the SP values obtained under shop conditions. The dimensions of the ingots were

Card 2/3

137-58-6-12145

The Effect of Rolling Rate, Temperature, and Degree of Deformation (cont.)

85x270x550 mm. The values of the SP obtained in two series of such experiments coincided satisfactorily.

TITLE: Spreading of Nickel and MN19 German Silver (Ushireniye nikelya i mel'khiora MN19)

PERIODICAL: Tr. Gos. n.-i. i proyekt. in-ta po obrabotke tsvetn. met. , 1957, Nr 17, pp 38-46

ABSTRACT: An investigation was made of the quantitative effect of the particular rolling (R) procedure on the spreading (S) of Ni and of German silver, and certain existing formulas were recommended which yield results pertinent to the given circumstances. R of Ni billets measuring 85x275 and 85x215 mm was performed on a 750 mill, R speed being 1.8 m/sec, and the temperature at the start of R being 1090°. The investigation showed that the width of the strip affected S when $B/H < 4$. The effects of temperature, speed, and degree of deformation were investigated in the R of billets in which $B/H = 1-1.5$, with 10, 20, and 30 percent reductions at temperatures of 1000-1200° for Ni and 850-1050° for German silver. R was performed on a 400 mm mill. Analysis of the data showed that, under the given conditions, the tempera-

Card 1/2

137-58-4-7032

Spreading of Nickel and MN19 German Silver

ture and rate of R had virtually no effect on S. As the degree of deformation was raised from 10 to 30 percent, the S of Ni and German silver increased from 3 to 10 percent. The investigation showed that the Petrov formula is valid for specimens in which the $B/H=1-1.5$ ratio obtains. The Kheyn and the Gubkin formulas give somewhat different results, and the Sedlachek and Ekelund equations yield excessively elevated results. The Kheyn equation, with the C coefficient constant at 1.54, is recommended for calculation of S at B/H ratios of up to 6.

lubricants on the purity and strength properties of ultra-pure aluminum wire was determined. The initial purity of the metal was in the region of 99.996 to 99.99987%. Microphotographs of wire specimens are presented. The experimental results are shown in graphs and tables (see Fig. 1).

Fig. 1. Influence of low temperatures on the mechanical properties of zone-refined aluminum. σ_b strength limit, δ plasticity coefficient.

It was found that wire of 0.1 to 0.08 mm in diameter may be obtained from 99.9992% pure aluminum without any difficulty. But obtaining wire of higher purity required

Card 2/3

L 24428-66

ACC NR: AT6006482

low drawing temperatures (-60 to -70C) and drawing speeds on the order of 30--40 m/sec in order to prevent recrystallization of the metal. The plasticity of the wire was found to increase and its strength to decrease with increase in the purity of the aluminum. The use of diamond dyes and appropriate dye lubricants (the lubricant "Alyudro 6, specimen 1" was found to be the most suitable of the ten lubricants tested) insures the retention of the initial high purity of the metal in the wire. Orig. art. has: 1 table and 6 graphs.

TITLE: Basic parameters of wire protection from high-purity aluminum

SOURCE: Ref. zh. Metallurgiya, Abs. 5D412

REF SOURCE: Tr. Gos. n. -i. i proyekt. in-ta splavov i obrabotki tsvetn. met.,
vyp. 24, 1965, 284-297

TOPIC TAGS: wire, fine wire, wire protection, wire drawing

ABSTRACT: Wire 0.1 to 0.08-mm in diameter can be drawn from aluminum (99.9992%) by single-stage or multistage machines. However, for drawing wire (< 1.2 mm in diameter) from high-purity aluminum special conditions are necessary. Drawing must be done at -60C to 70C at speeds which eliminate the possibility of recrystallization (30 to 40 m/sec). The lowering of temperature of metal to -60C to 70C increases tensile strength of aluminum by 20 to 25%, with practically no changes in length. Based on stability conditions of the drawing process and the safety factors at room temperature, 18-25% reductions in one pass are recommended. It was determined that the technology of wire production
